redhat

VERT.X

A TOOLKIT TO BUILD DISTRIBUTED REACTIVE SYSTEMS

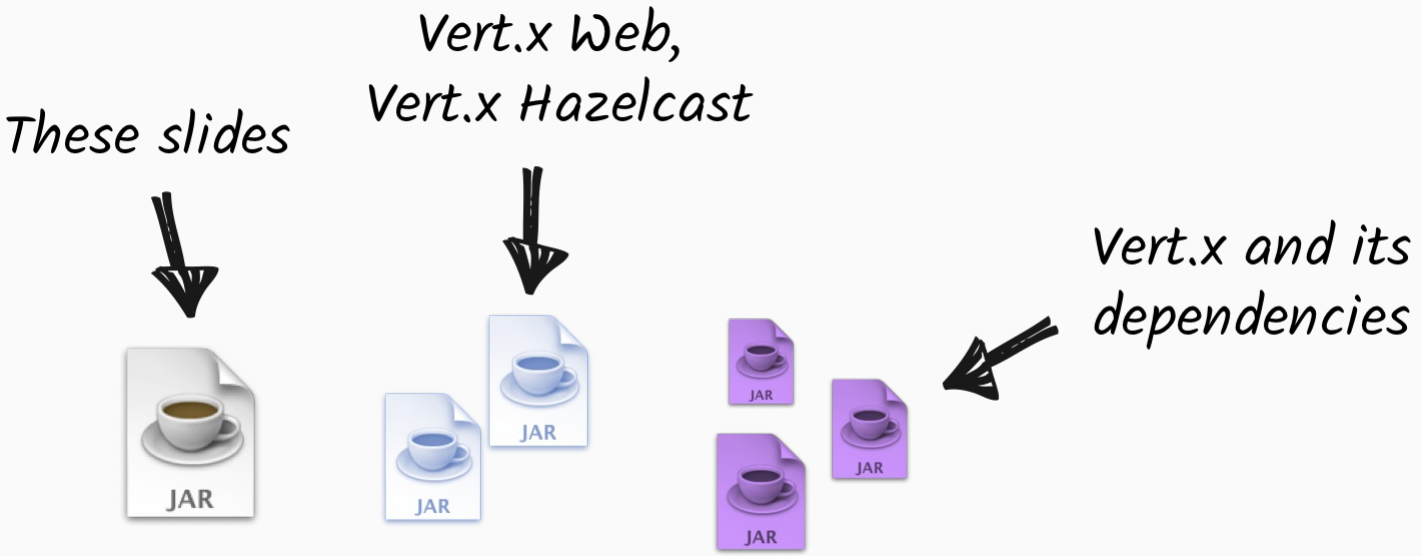
CLEMENT ESCOFFIER

Vert.x Core Developer, Red Hat

VERT.X IS A **TOOLKIT** TO BUILD **DISTRIBUTED** AND **REACTIVE** APPLICATIONS ON TOP OF THE **JVM** USING AN **ASYNCHRONOUS NON-BLOCKING** DEVELOPMENT MODEL.

TOOLKIT

- Vert.x is a plain boring **jar**
- Vert.x components are plain boring jars
- Your application depends on this set of jars (classpath, *fat-jar*, ...)



DISTRIBUTED

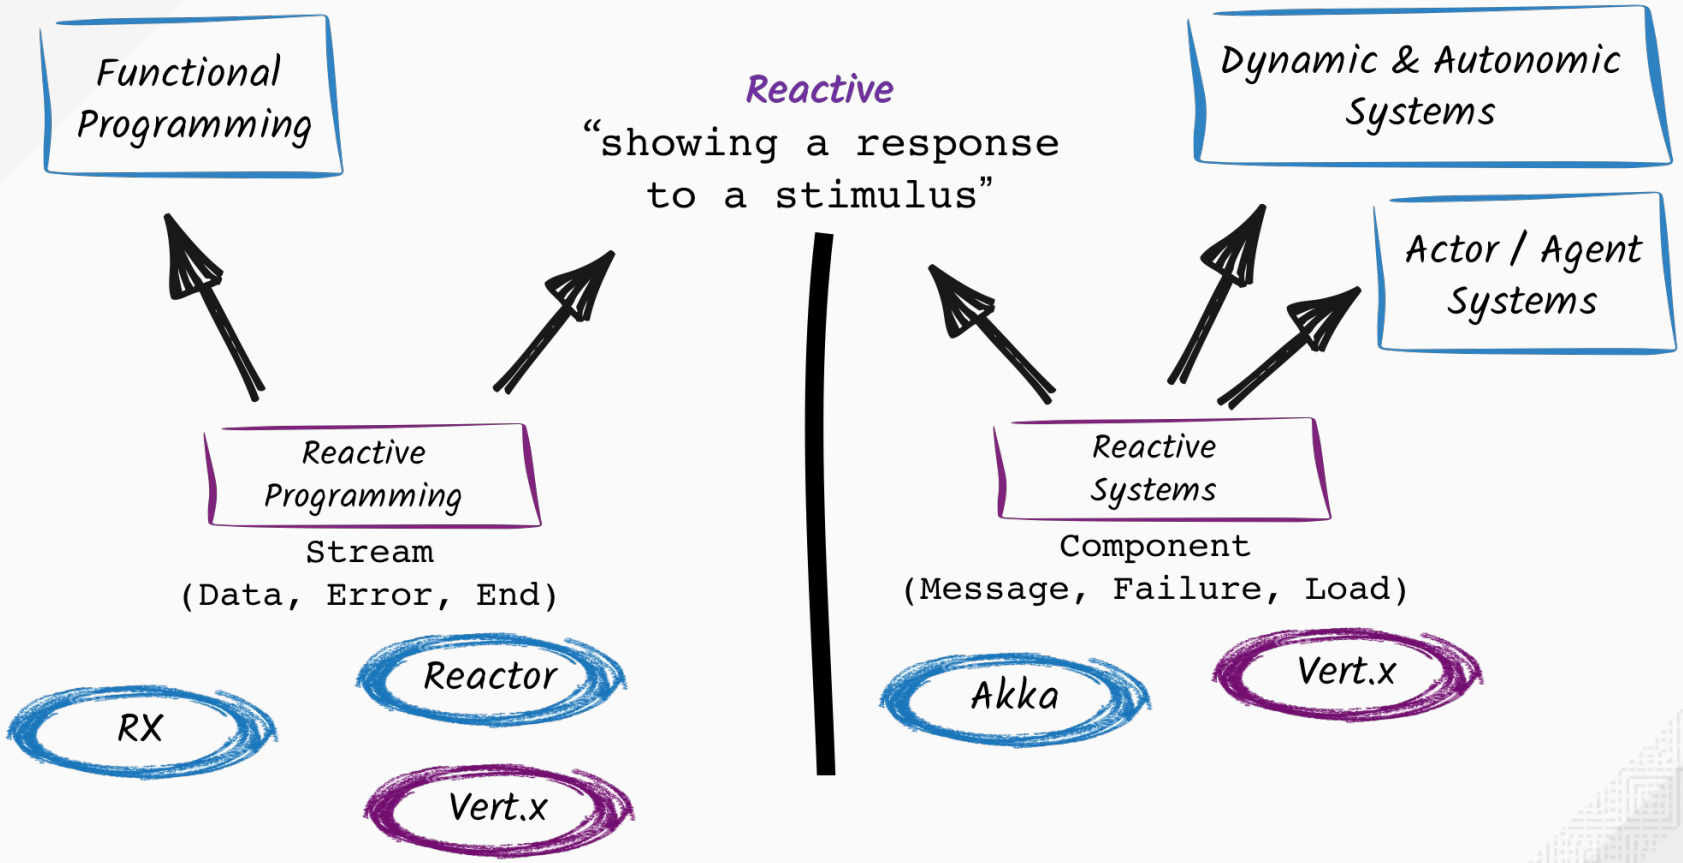
“ You know you have a distributed system when the crash of a computer you've never heards of stops you from getting any work done.” (Leslie Lamport)

REACTIVE SYSTEMS

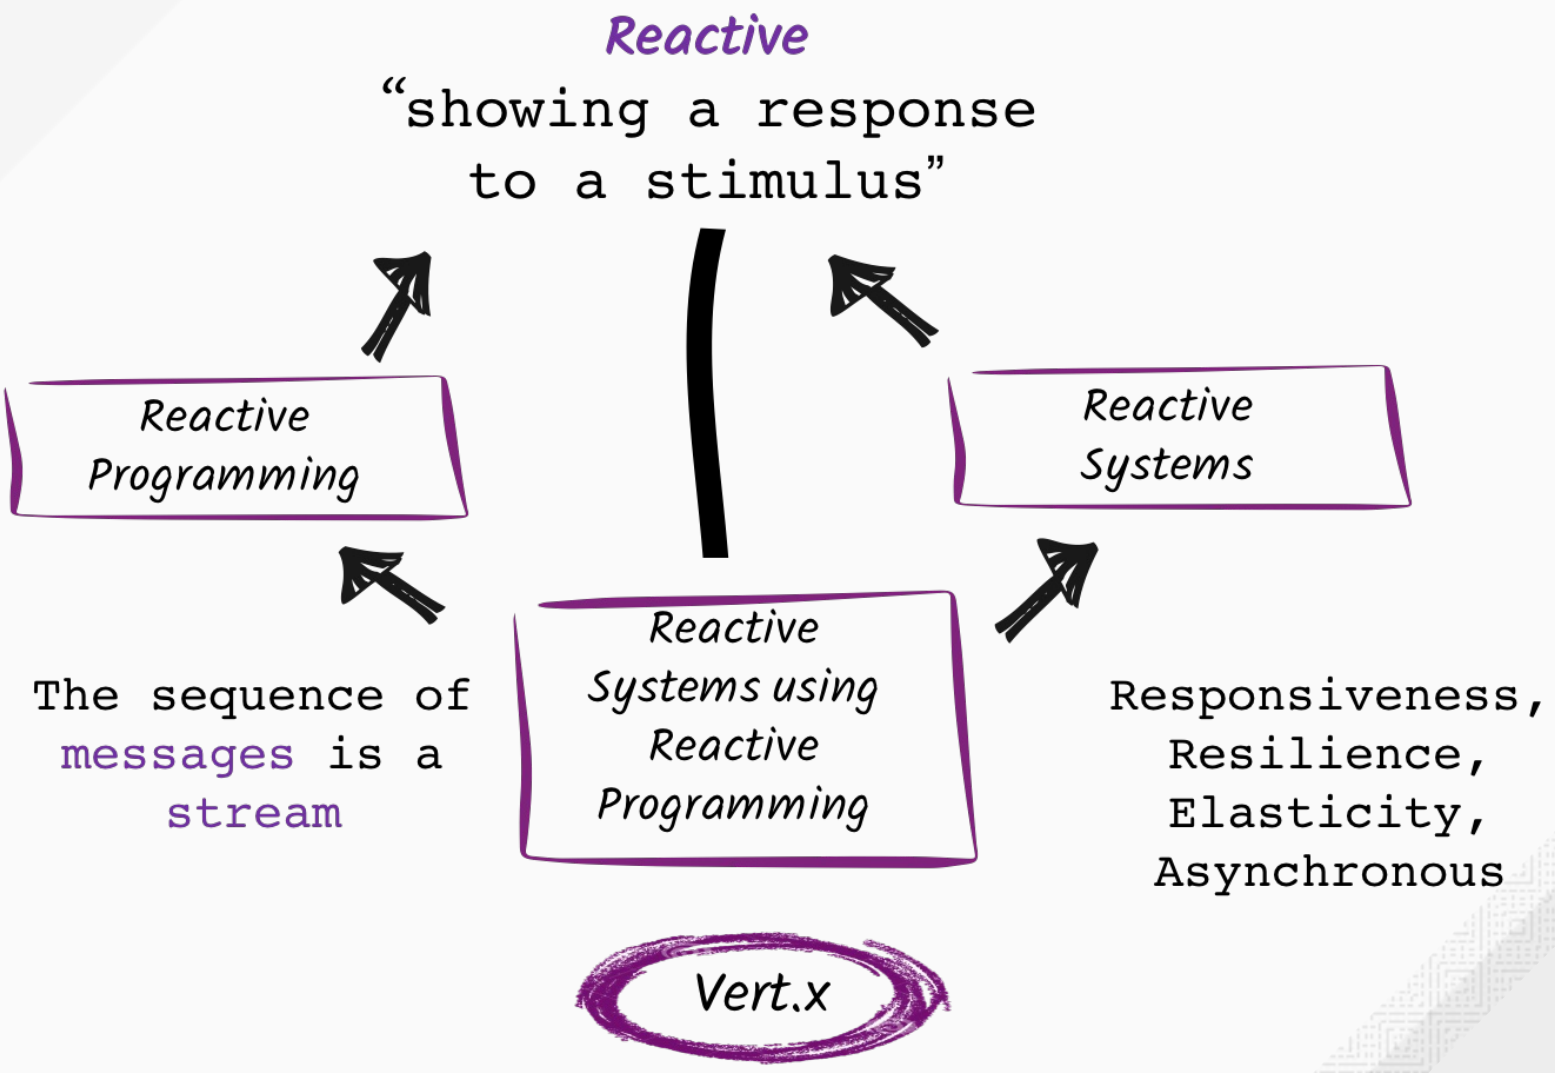
- **Responsive** - they respond in an *acceptable* time
- **Elastic** - they scale up and down
- **Resilient** - they are designed to handle failures *gracefully*
- **Asynchronous** - they interact using async messages

http://www.reactivemanifesto.org/

REACTIVE SYSTEMS != REACTIVE PROGRAMMING



REACTIVE SYSTEMS + REACTIVE PROGRAMMING



POLYGLOT

Vert.x applications can be developed using

- Java
- Groovy
- Ruby (JRuby)
- JavaScript (Nashorn)
- Ceylon
- *Scala*
- *Kotlin*

VERT.X

A toolkit to build distributed systems & microservices

VERT.X

Build **distributed** systems:

- Do not hide the **complexity**
- **Failure** as first-class citizen
- Provide the building blocks, not an all-in-one solution

WHAT DOES VERT.X PROVIDE ?

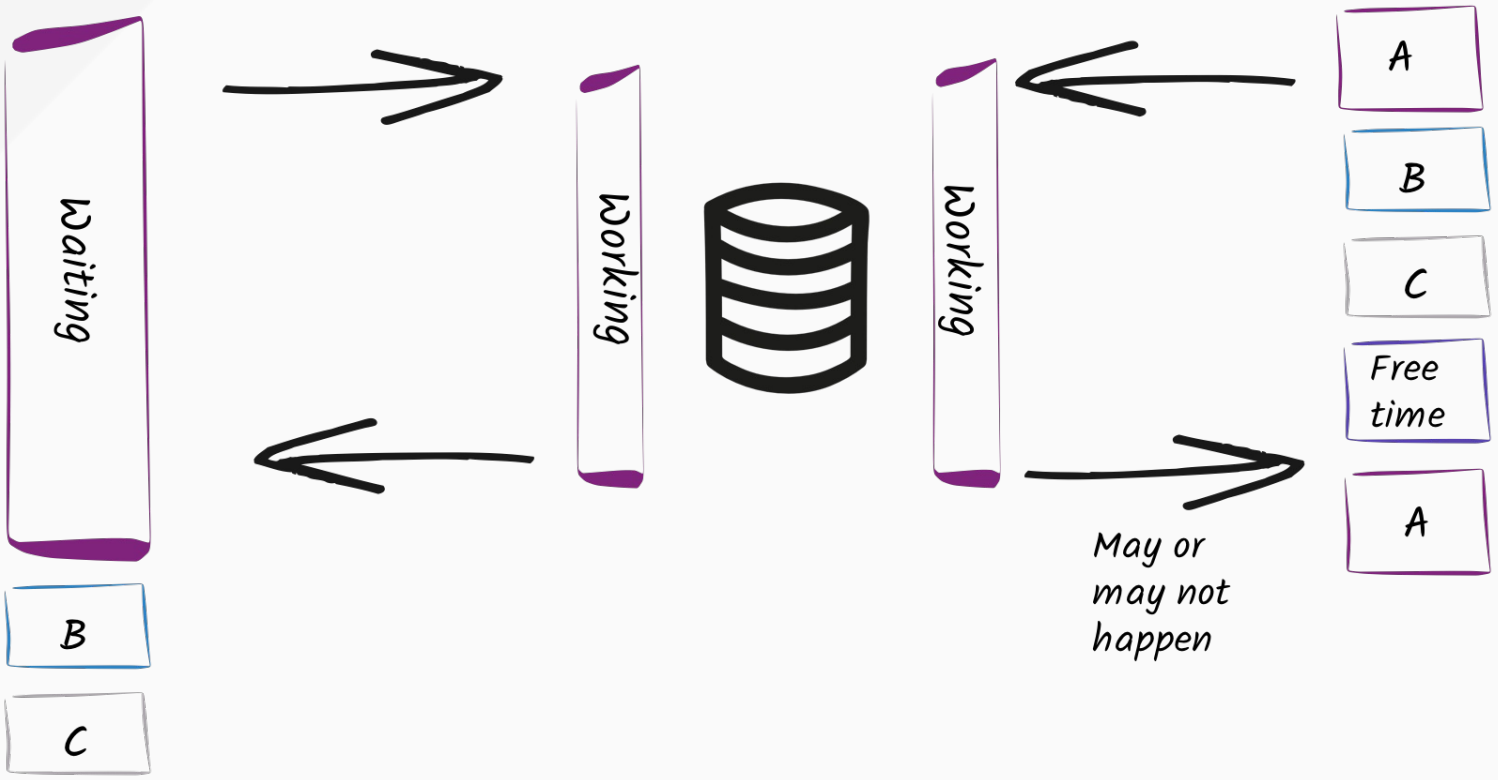
- TCP, UDP, HTTP 1 & 2 servers and clients
- (non-blocking) DNS client
- Clustering
- Event bus (messaging)
- Distributed data structures
- (built-in) Load-balancing
- (built-in) Fail-over
- Pluggable service discovery, circuit-breaker
- Metrics, Shell

REACTIVE

Build **reactive distributed** systems:

- **Responsive** - fast, is able to handle a large number of events / connections
- **Elastic** - scale up and down by just starting and stopping nodes, round-robin
- **Resilient** - failure as first-class citizen, fail-over
- **Asynchronous message-passing** - asynchronous and non-blocking development model

ASYNCHRONOUS & NON-BLOCKING



ASYNCHRONOUS & NON-BLOCKING

```
// Synchronous development model
X x = doSomething(a, b);

// Asynchronous development model - callback variant
doSomething(a, b, // Params
   ar -> {       // Last param is a Handler<AsyncResult<X>>
     // Result handler
   });

// Asynchronous development model - future variant
Future<X> future = doSomething(a, b);
future.setHandler(
   ar -> {  /* Completion handler */ });
```

REQUEST - REPLY INTERACTIONS

HTTP, TCP, RPC...

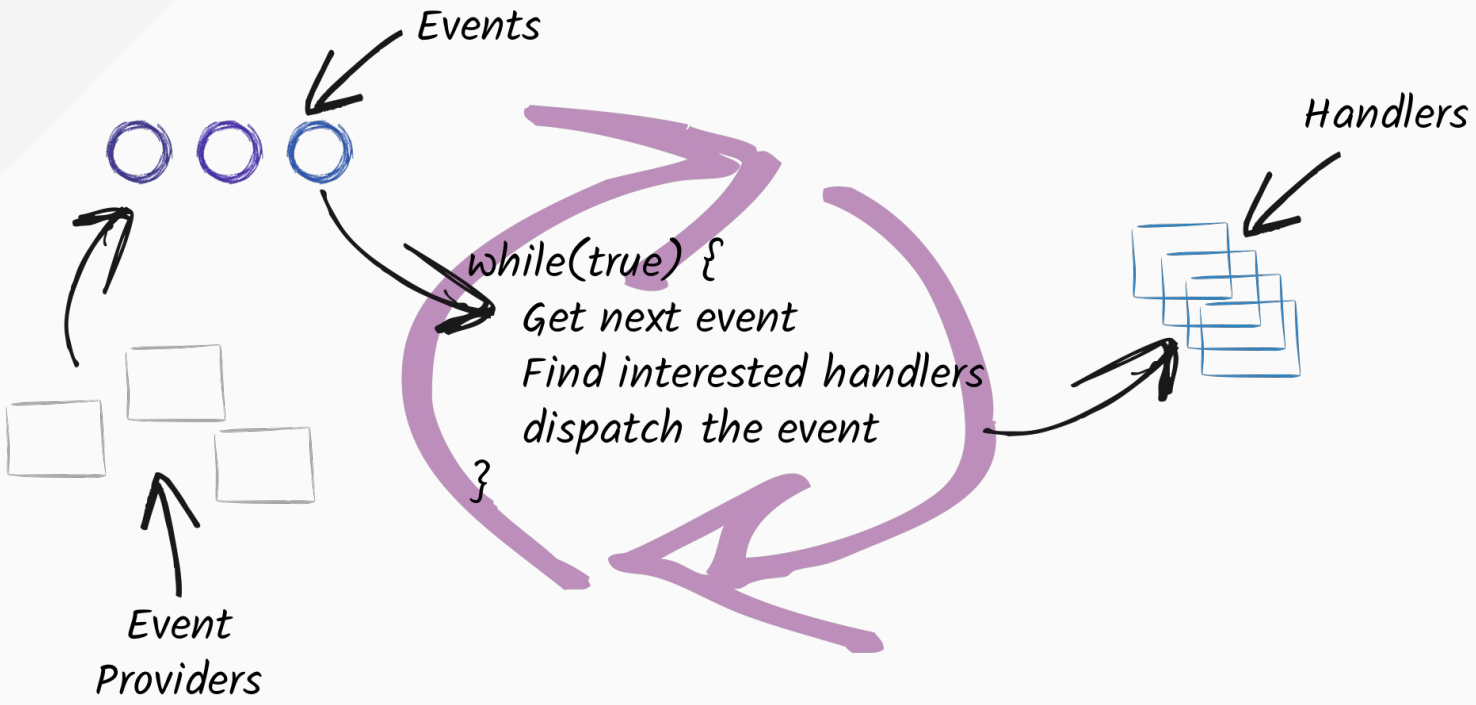
VERT.X HELLO WORLD

```
Vertx vertx = Vertx.vertx();
vertx.createHttpServer()
  .requestHandler(request -> {
    // Handler receiving requests
    request.response().end("World !");
  })
  .listen(8080, ar -> {
    // Handler receiving start sequence completion (AsyncResult)
    if (ar.succeeded()) {
      System.out.println("Server started on port "
        + ar.result().actualPort());
    } else {
      ar.cause().printStackTrace();
    }
  });
```

VERT.X HELLO WORLD

Invoke

EVENT LOOPS



Events
Handlers
while(true) {
Get next event
Find interested handlers
dispatch the event
}
Event
Providers

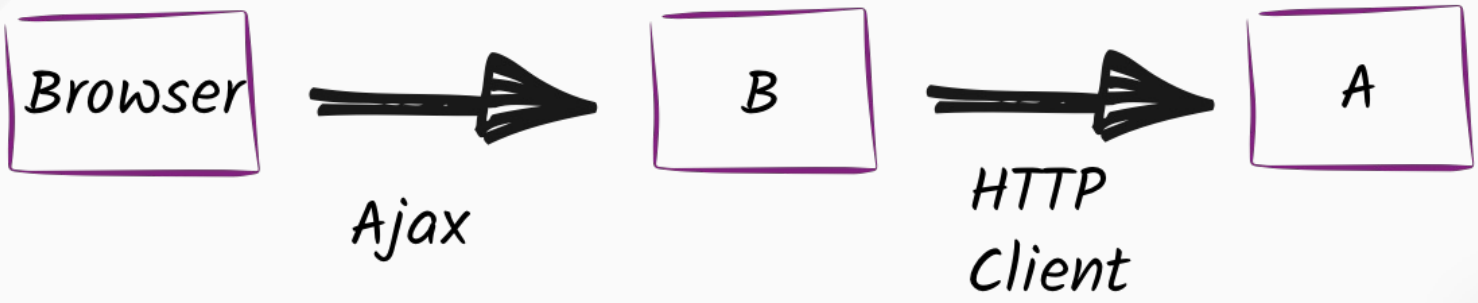
VERT.X ASYNC HTTP CLIENT

```
HttpClient client = vertx.createHttpClient(
        new HttpClientOptions()
                .setDefaultHost("localhost")
                .setDefaultPort(8081));

client.getNow("/", response -> {
  // Handler receiving the response

  // Get the content
  response.bodyHandler(buffer -> {
    // Handler to read the content
  });
});
```

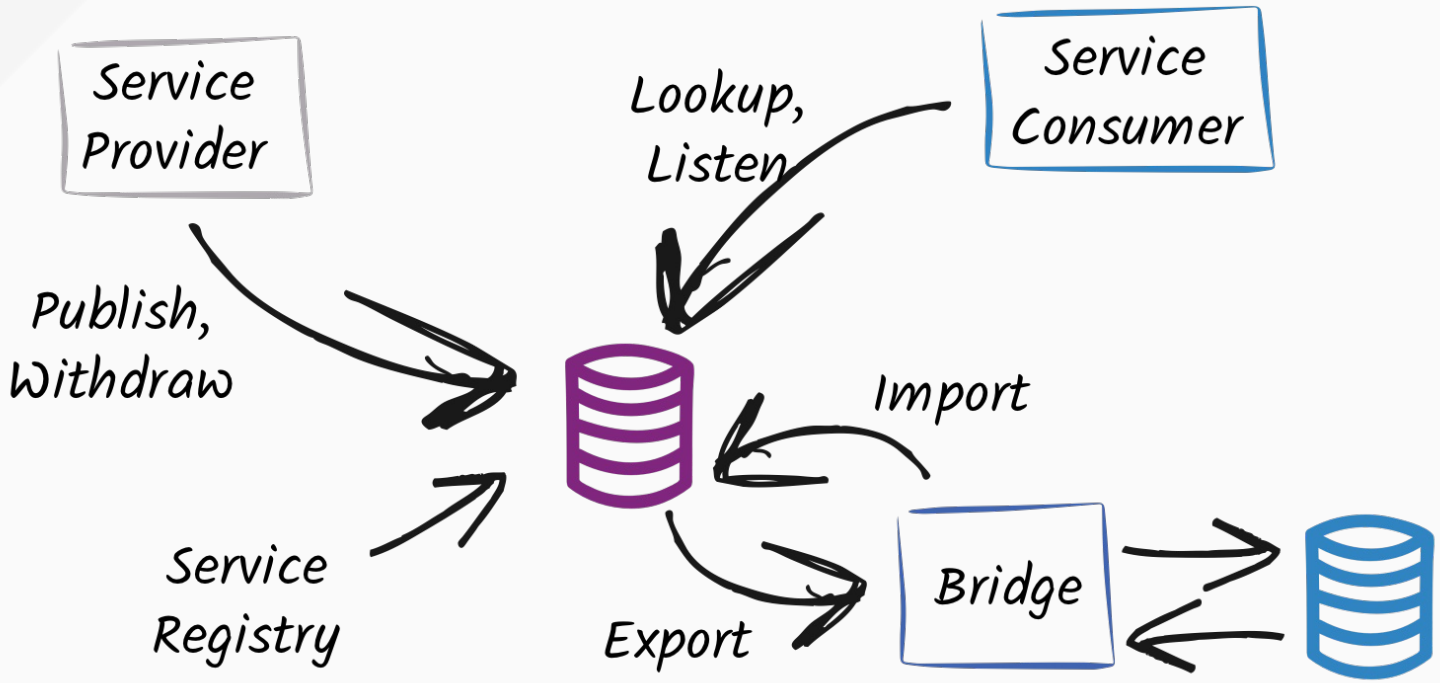
CHAINED HTTP REQUESTS



Invoke

SERVICE DISCOVERY

Locate the services, environment-agnostic



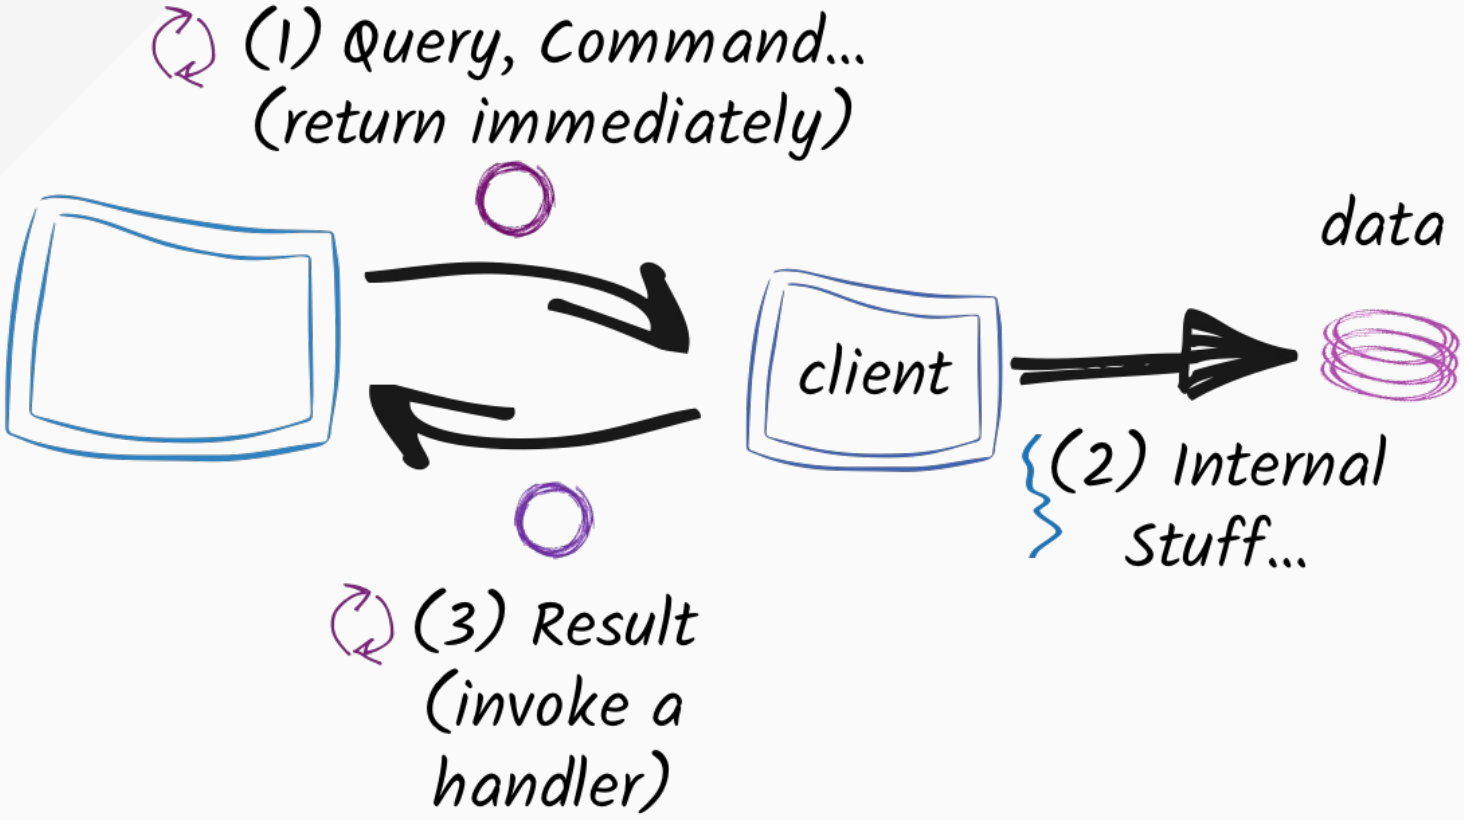
SERVICE DISCOVERY

```
HttpEndpoint.getClient(discovery,
    new JsonObject().put("name", "vertx-http-server"),
    result -> {
      if (result.failed()) {
        rc.response().end("D'oh no matching service");
        return;
      }
      HttpClient client = result.result();
      client.getNow("/", response -> {
        response.bodyHandler(buffer -> {
          rc.response().end("Hello " + buffer.toString());
        });
      });
    });
```

INTERACTING WITH BLOCKING SYSTEMS

```
vertx.executeBlocking(
  future -> {
     // Executed using a worker thread
  },
  asyncResult -> {
    // Executed in the event loop thread
    if (asyncResult.failed()) {
     // ...
    } else {
     // ...
    }
}
);
```

INTERACTING WITH BLOCKING SYSTEMS



MESSAGING

The eventbus - the spine of Vert.x applications...

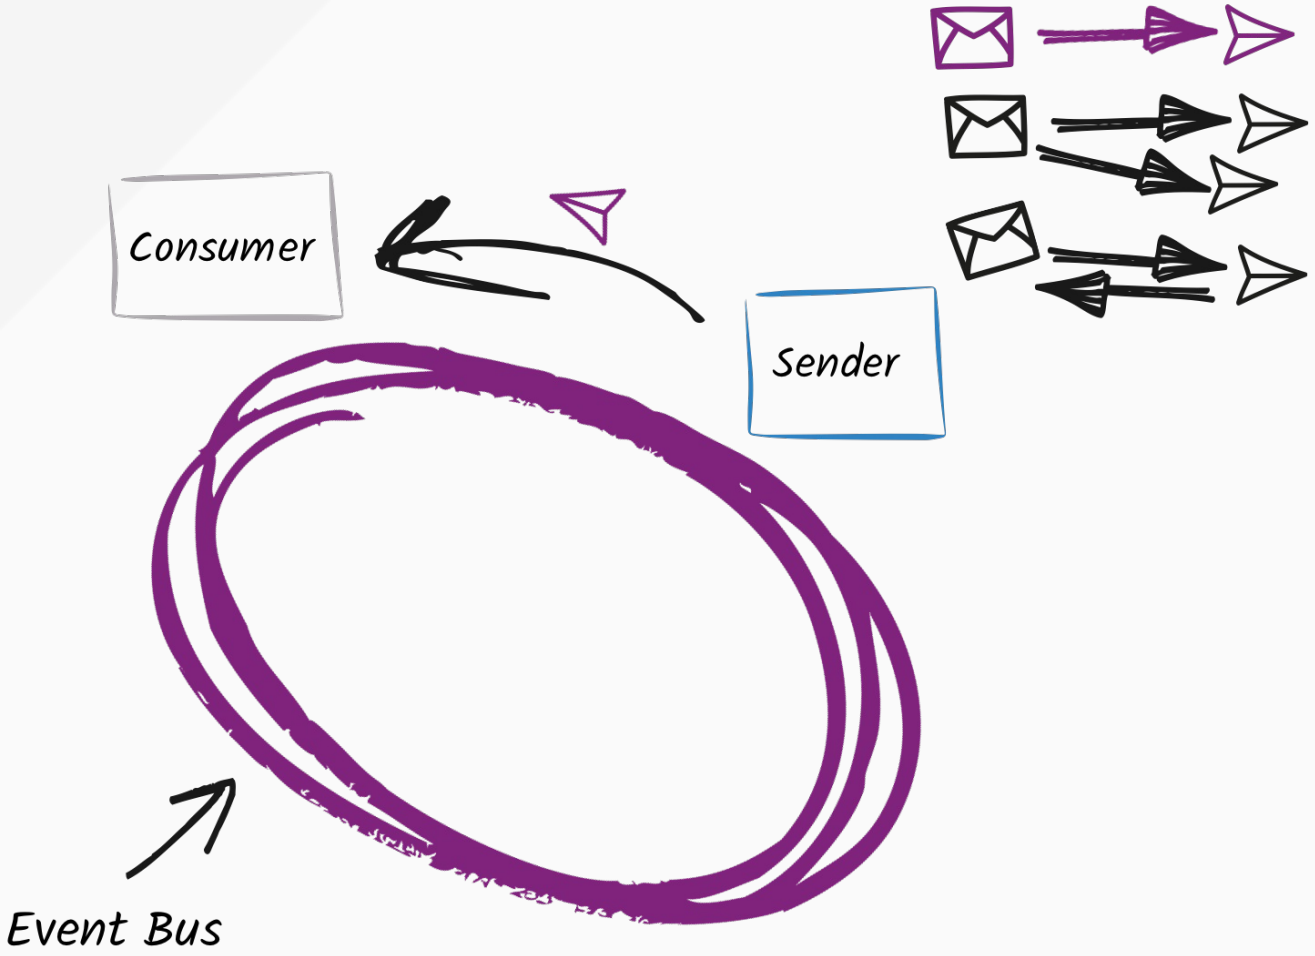
THE EVENT BUS

The event bus is the **nervous system** of vert.x:

- Allows different components to communicate regardless
  - the implementation language and their location
  - whether they run on vert.x or not (using bridges)

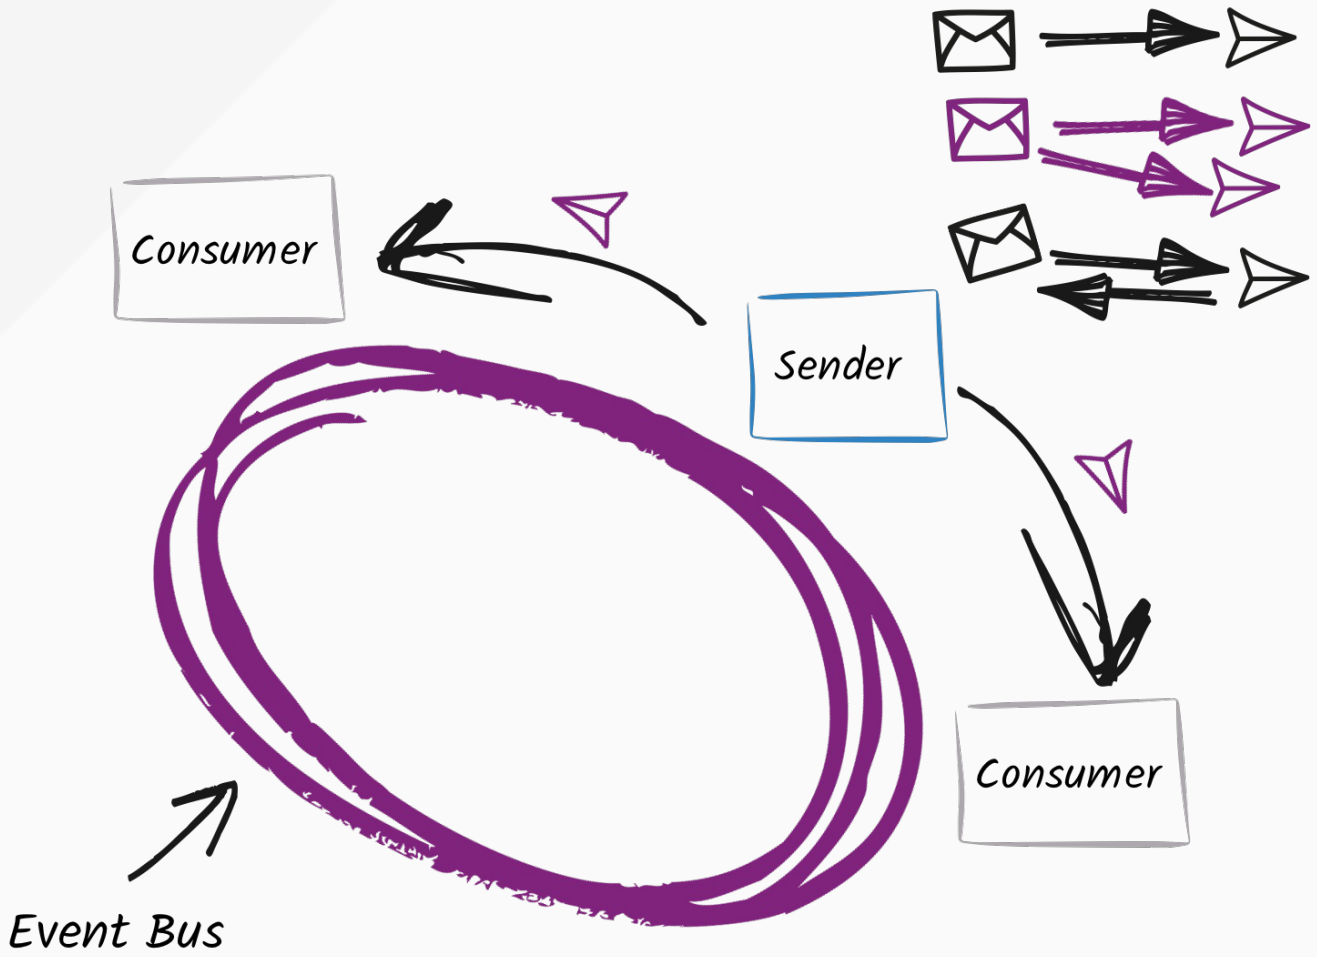
- **Address**: Messages are sent to an address
- **Handler**: Messages are received by Handlers.

POINT TO POINT



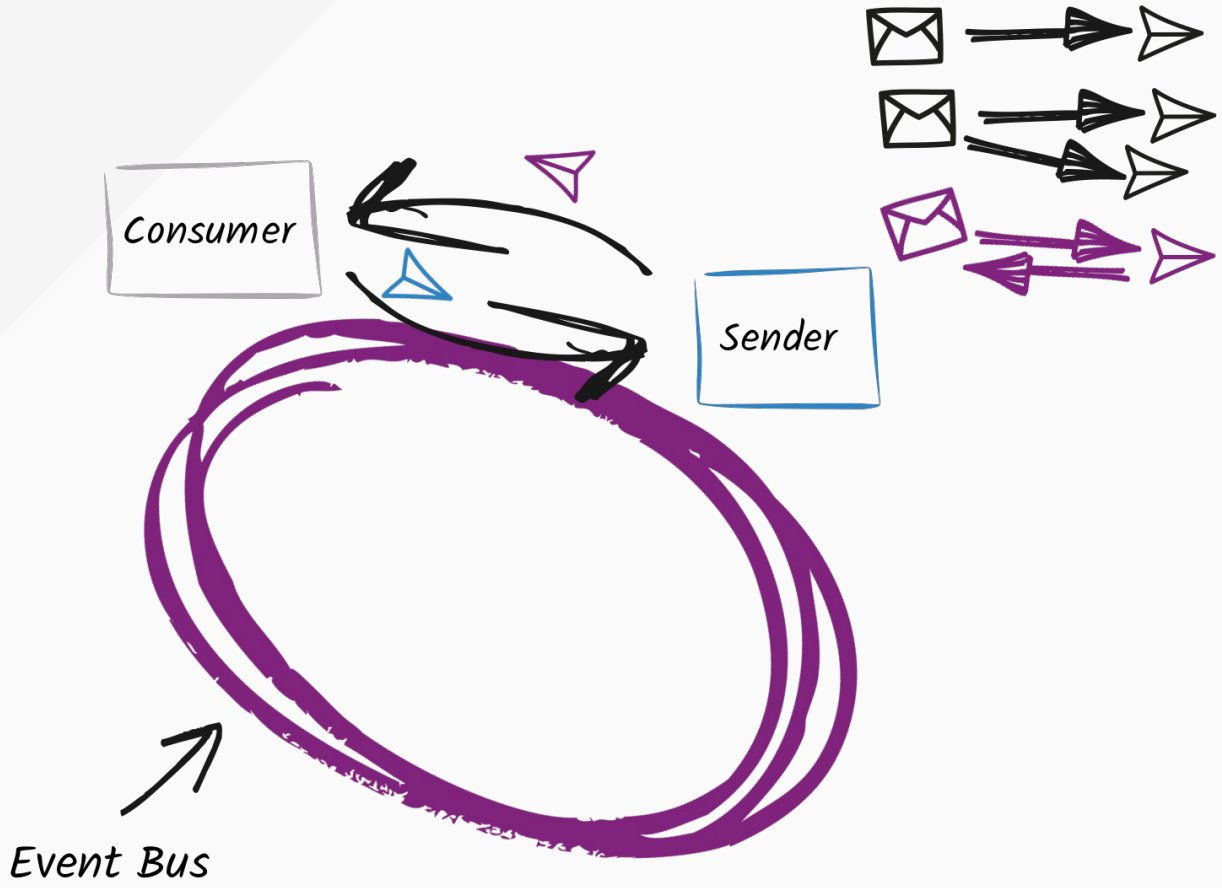
```
vertx.eventBus().send("address", "message");
vertx.eventBus().consumer("address", message -> {});
```

PUBLISH / SUBSCRIBE



```
vertx.eventBus().publish("address", "message");
vertx.eventBus().consumer("address", message -> {});
```

REQUEST / RESPONSE



```
vertx.eventBus().send("address", "message", reply -> {});
vertx.eventBus().consumer("address",
   message -> { message.reply("response"); });
```

FROM LOCAL TO CLUSTERED

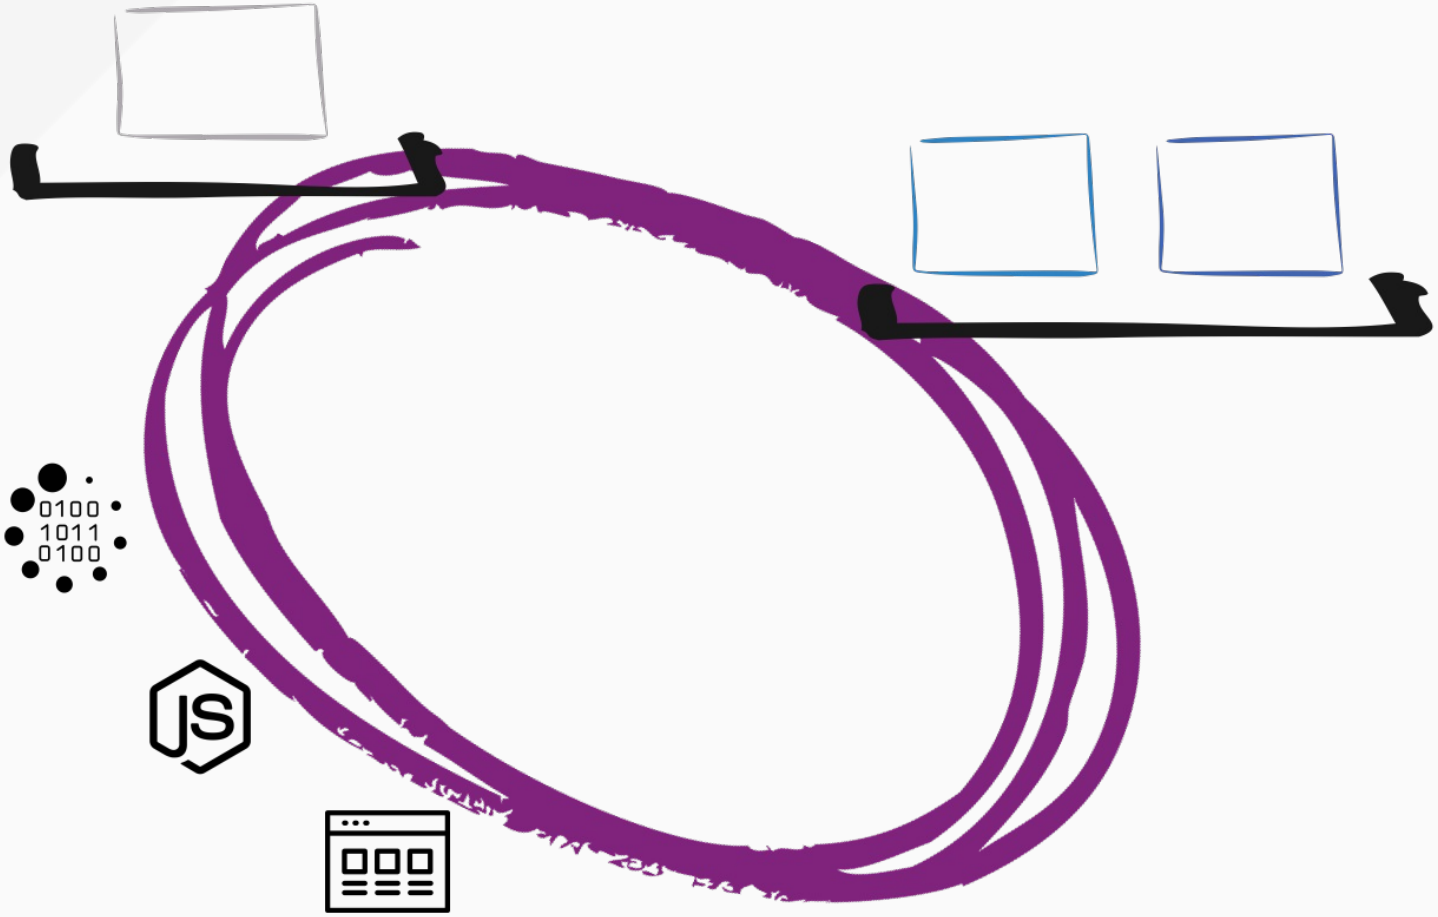
Vert.x instances form a **cluster**

```
Vertx.clusteredVertx(new VertxOptions(), result -> {
  if (result.failed()) {
    System.err.println("Cannot create a clustered vert.x : "
                + result.cause());
  } else {
    Vertx vertx = result.result();
    // ...
  }
});
```

The event bus is distributed on all the cluster members

DISTRIBUTED EVENT BUS

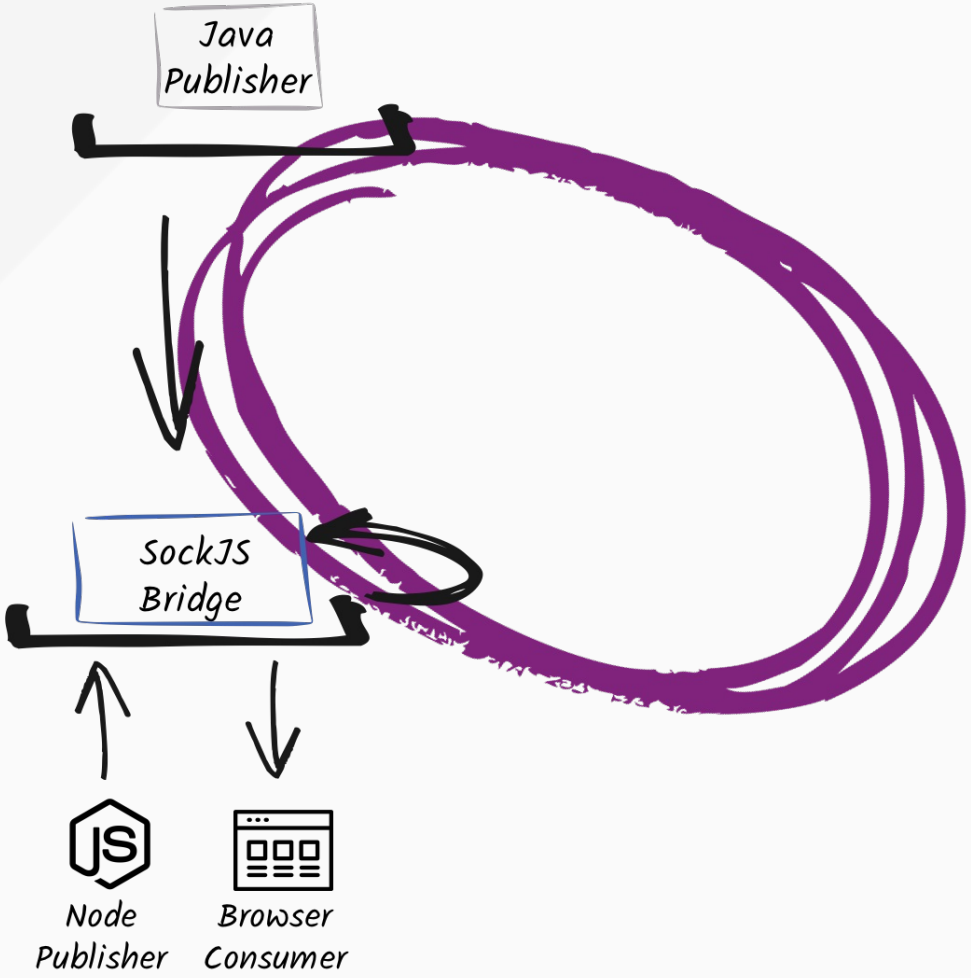
Almost anything can send and receive messages



DISTRIBUTED EVENT BUS

Let's have a java (Vert.x) app, and a node app sending data just here:

DISTRIBUTED EVENT BUS



EVENTBUS CLIENTS AND BRIDGES

Bridges

- SockJS: browser, node.js
- TCP: languages / systems able to open a TCP socket
- Stomp
- AMQP
- Apache Camel

Clients:

- Go, C#, C, Python, Swift...

RELIABILITY PATTERNS

Don't be fool, be prepared to fail

RELIABILITY

It's not about being bug-free or bullet proof,
we a **humans**.

It's about being prepared to **fail**,
and handling these **failures**.

MANAGING FAILURES

Distributed communication may fail

AsyncResult lets us manage these failures:

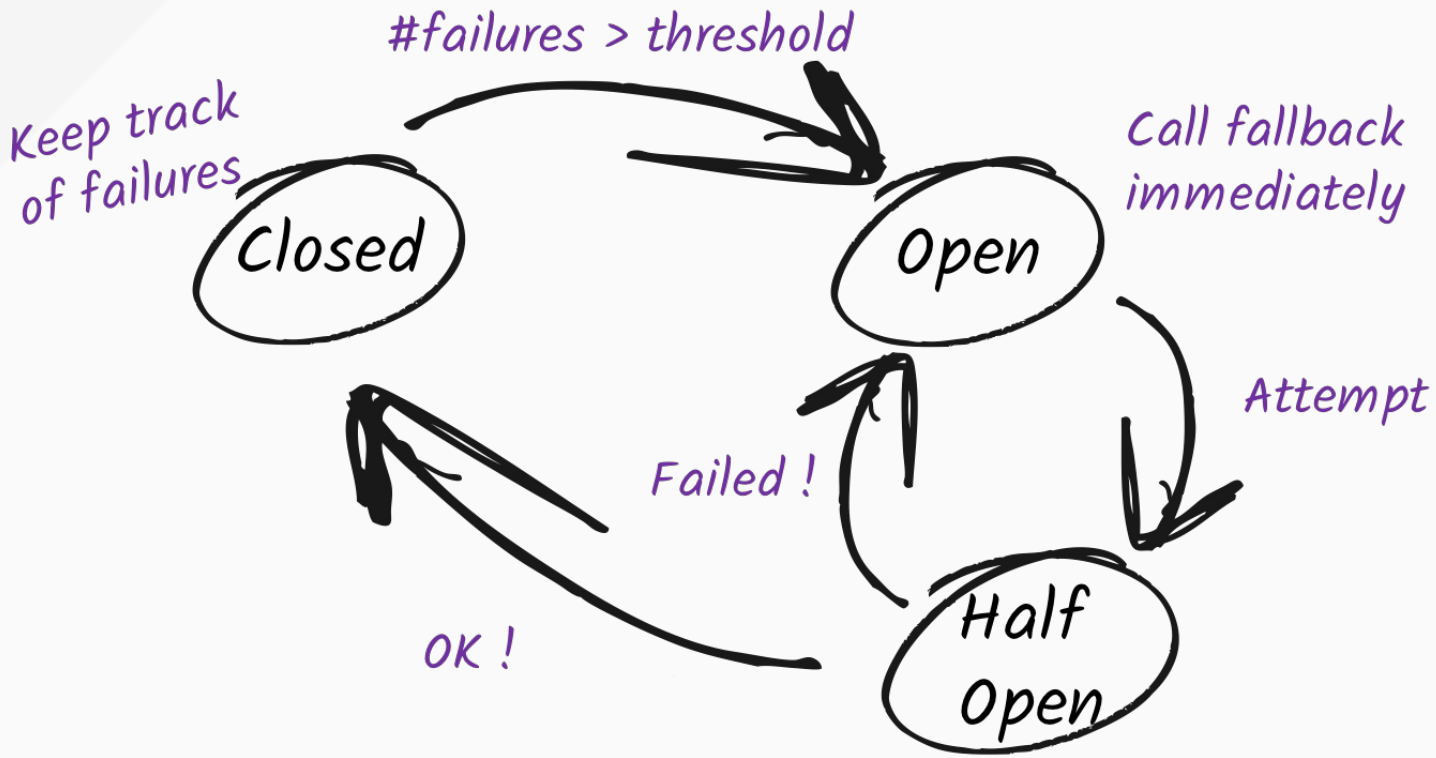
```
doSomethingAsync(param1, param2,
  ar -> {
    if (ar.failed()) {
      System.out.println("D'oh, it has failed !");
    } else {
      System.out.println("Everything fine ! ");
    }
});
```

MANAGING FAILURES

Adding timeouts

```
vertx.eventbus().send(..., ...,
  new DeliveryOptions().setSendTimeout(1000),
  reply -> {
    if (reply.failed()) {
      System.out.println("D'oh, he did not reply to me !");
    } else {
      System.out.println("Got a mail " + reply.result().body());
    }
});
```

CIRCUIT BREAKER

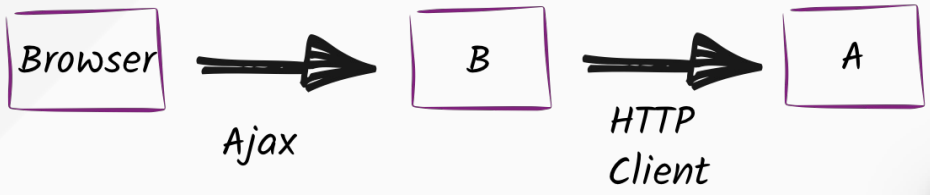


CIRCUIT BREAKER

```
cb.executeWithFallback(future -> {
  // Async operation
  client.get("/", response -> {
    response.bodyHandler(buffer -> {
      future.complete("Hello " + buffer.toString());
    });
  })
    .exceptionHandler(future::fail)
    .end();
  },

  // Fallback
  t -> "Sorry... " + t.getMessage() + " (" + cb.state() + ")"
)
  // Handler called when the operation has completed
  .setHandler(content -> /* ... */);
```

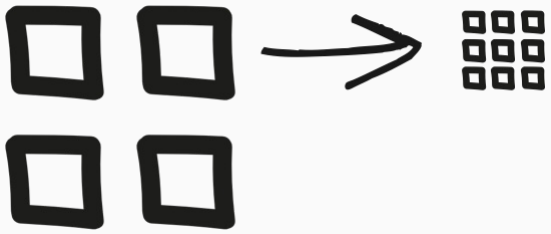
CIRCUIT BREAKER



Invoke

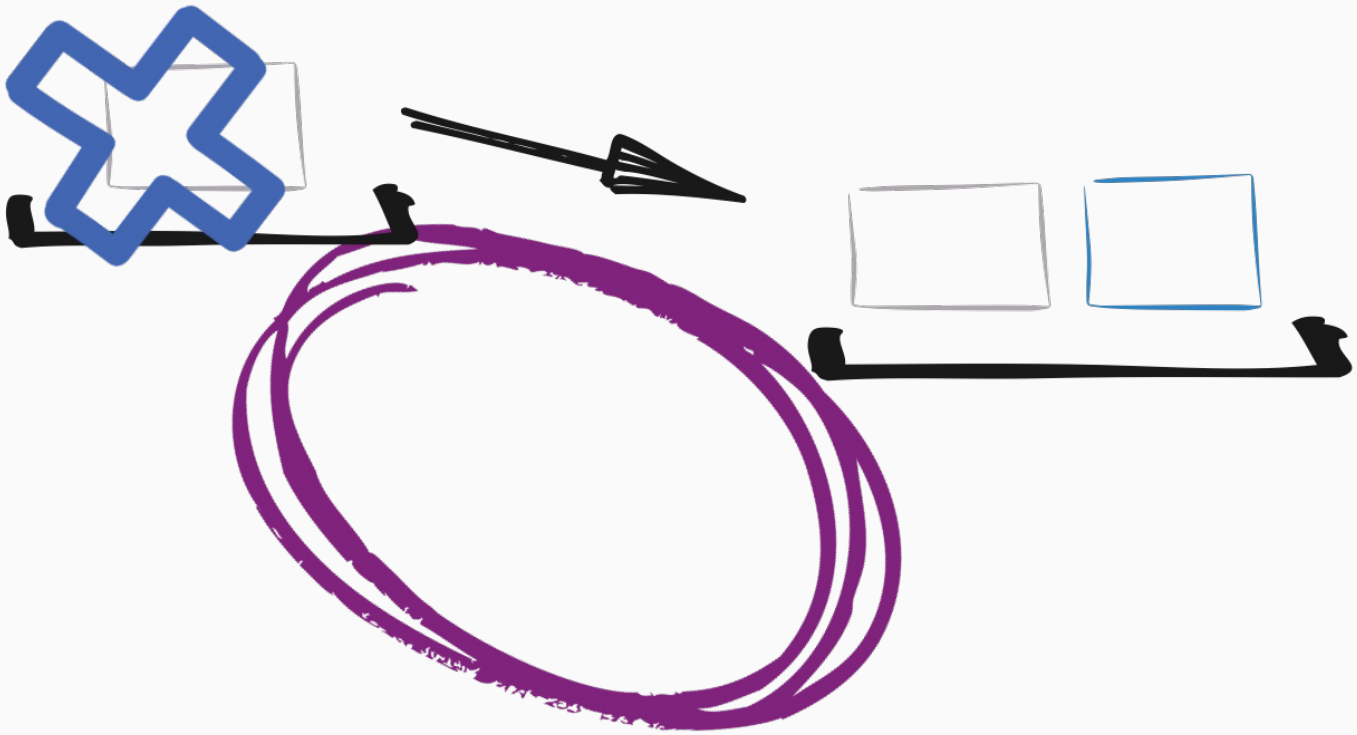
VERTICLE FAIL-OVER

- Verticles are chunk of code that get deployed and run by Vert.x
- Verticles can deploy other verticles
- Verticles can be written in Java, Groovy, JavaScript, Ruby, Ceylon...



VERTICLE FAIL-OVER

In **High-Availability** mode, verticles deployed on a node that **crashes** are redeployed on a sane node of the cluster.



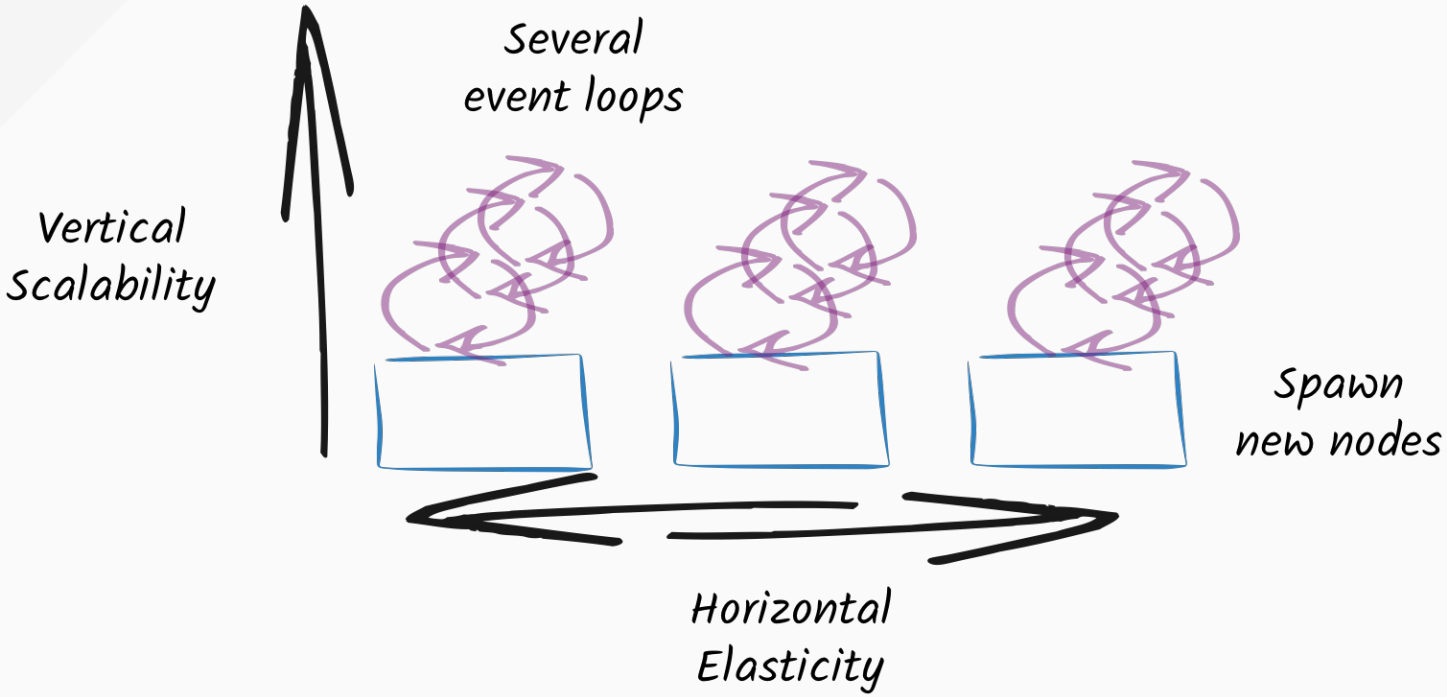
VERTICLE FAIL-OVER

Invoke

ELASTICITY PATTERNS

Be prepared to be famous

ELASTICITY PATTERNS

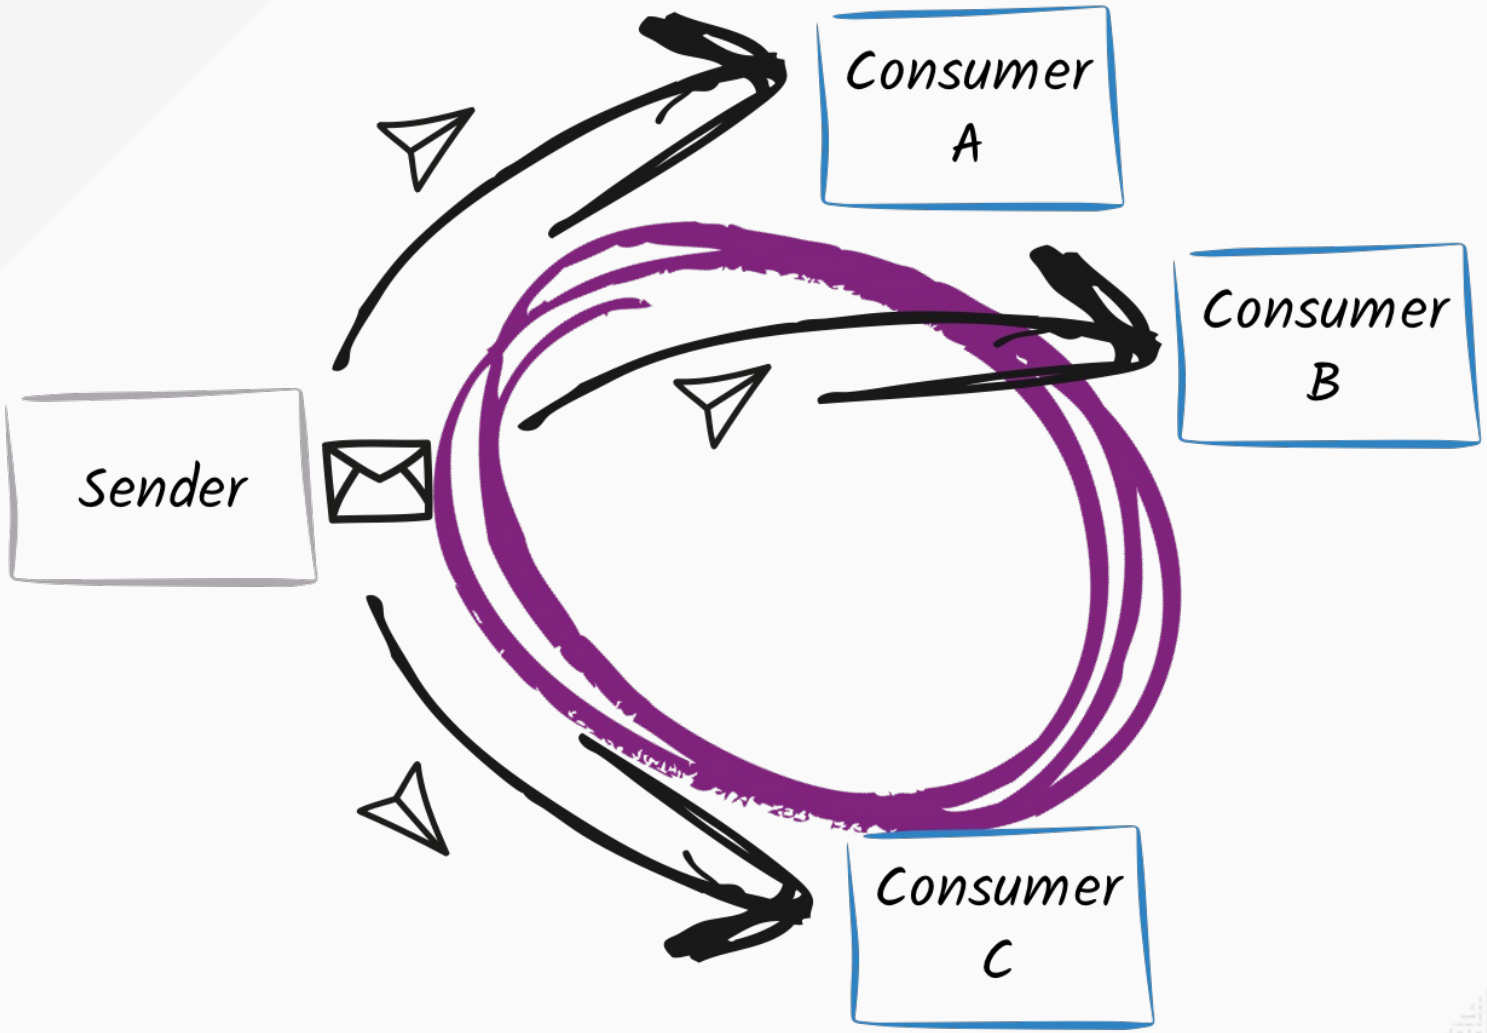


BALANCING THE LOAD

When several consumers listen to the same address, Vert.x dispatches the sent messages using a **round robin**.

So, to improve the scalability, just spawn a new node!

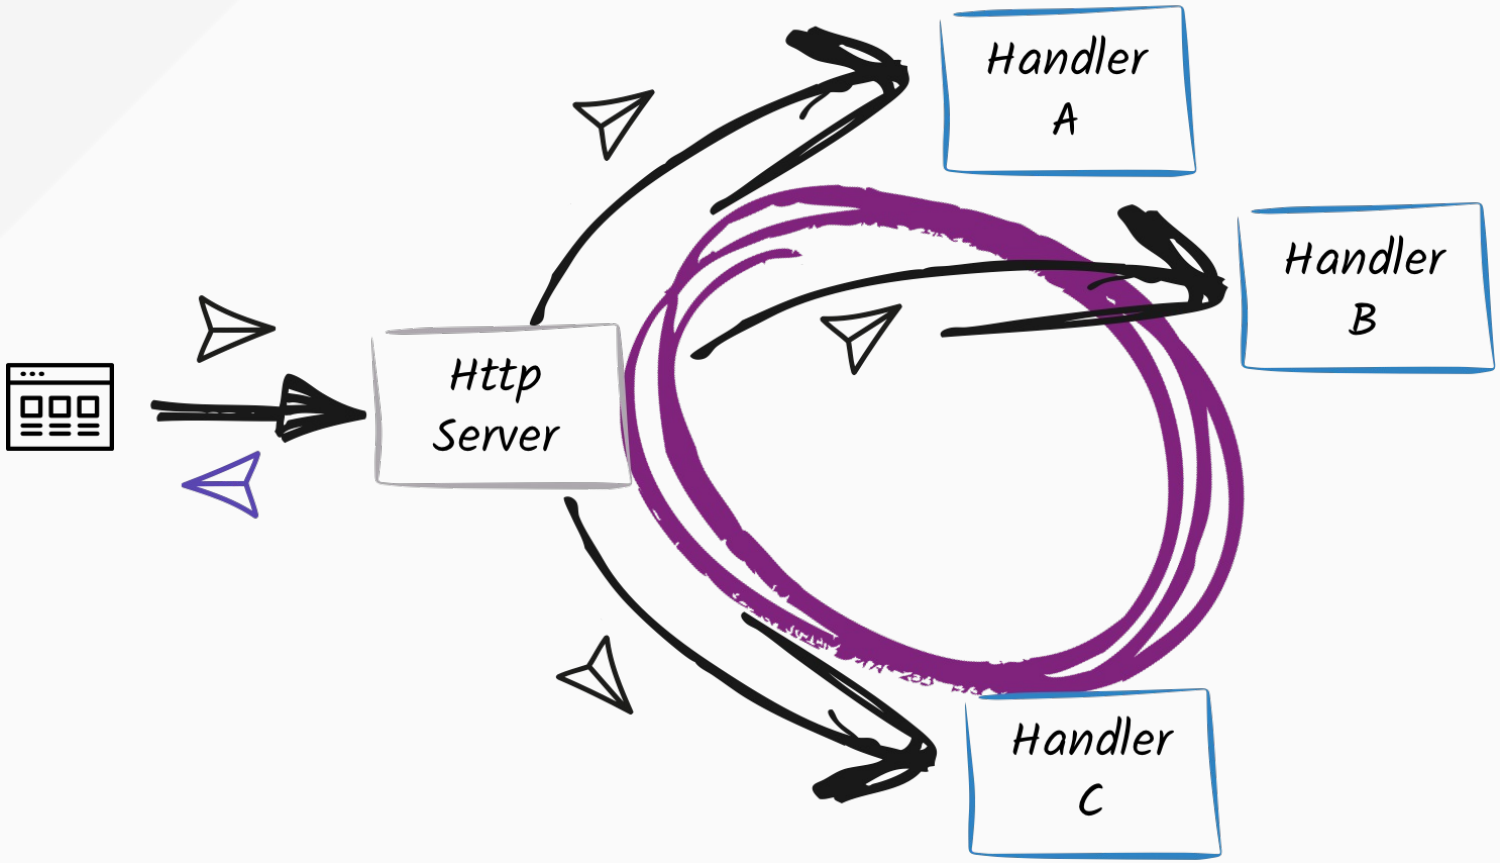
BALANCING THE LOAD



BALANCING THE LOAD

Invoke

SCALING HTTP

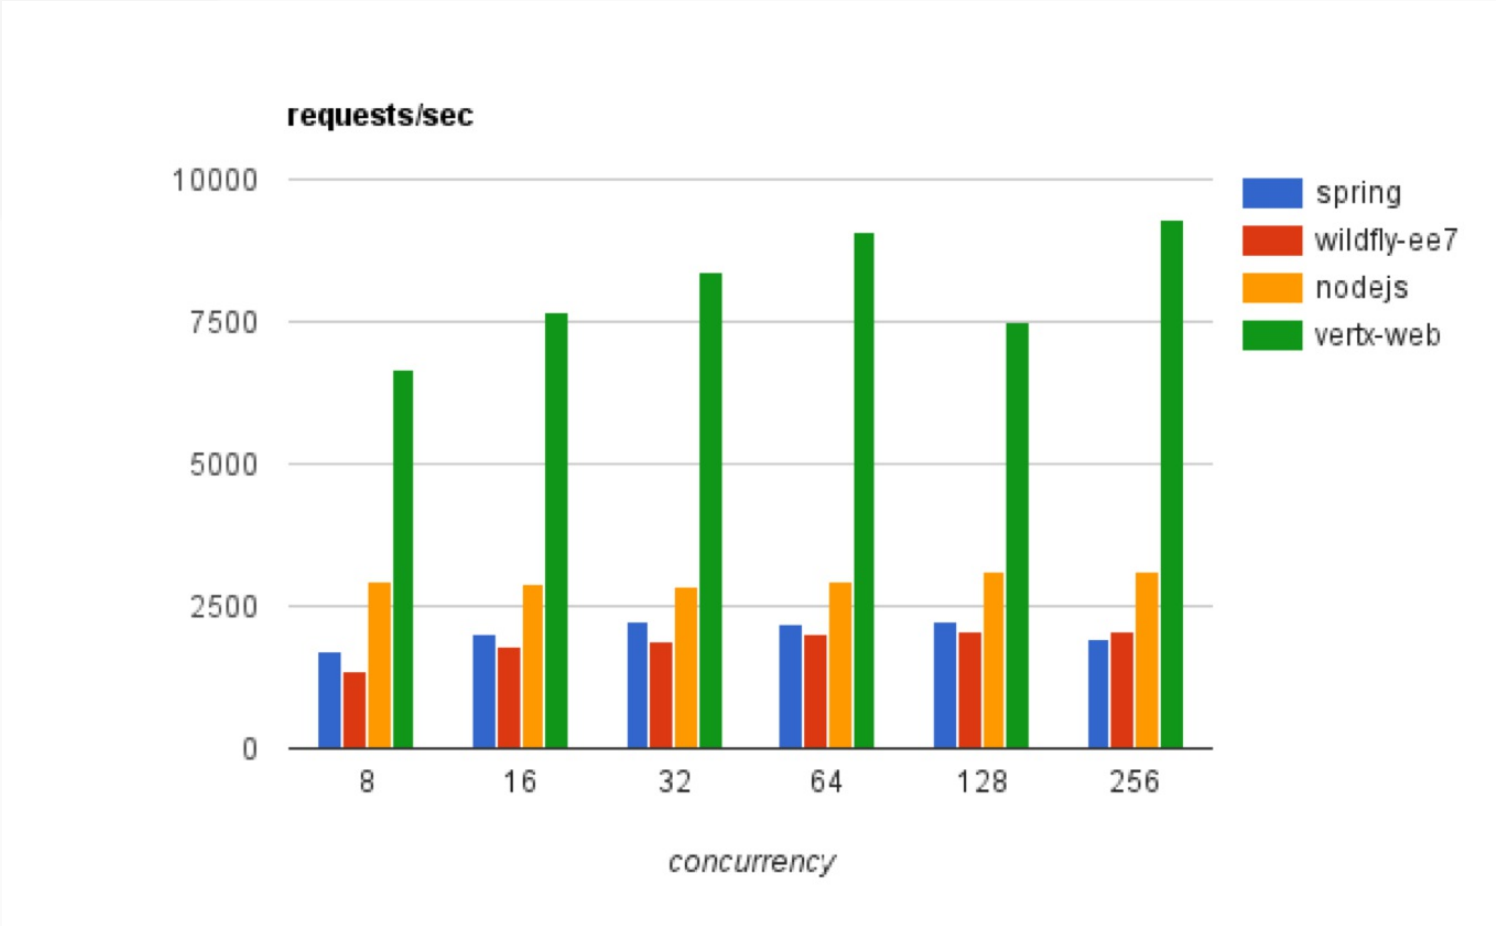


WHAT ABOUT PERFORMANCES ?

Because we do it well, and we do it fast

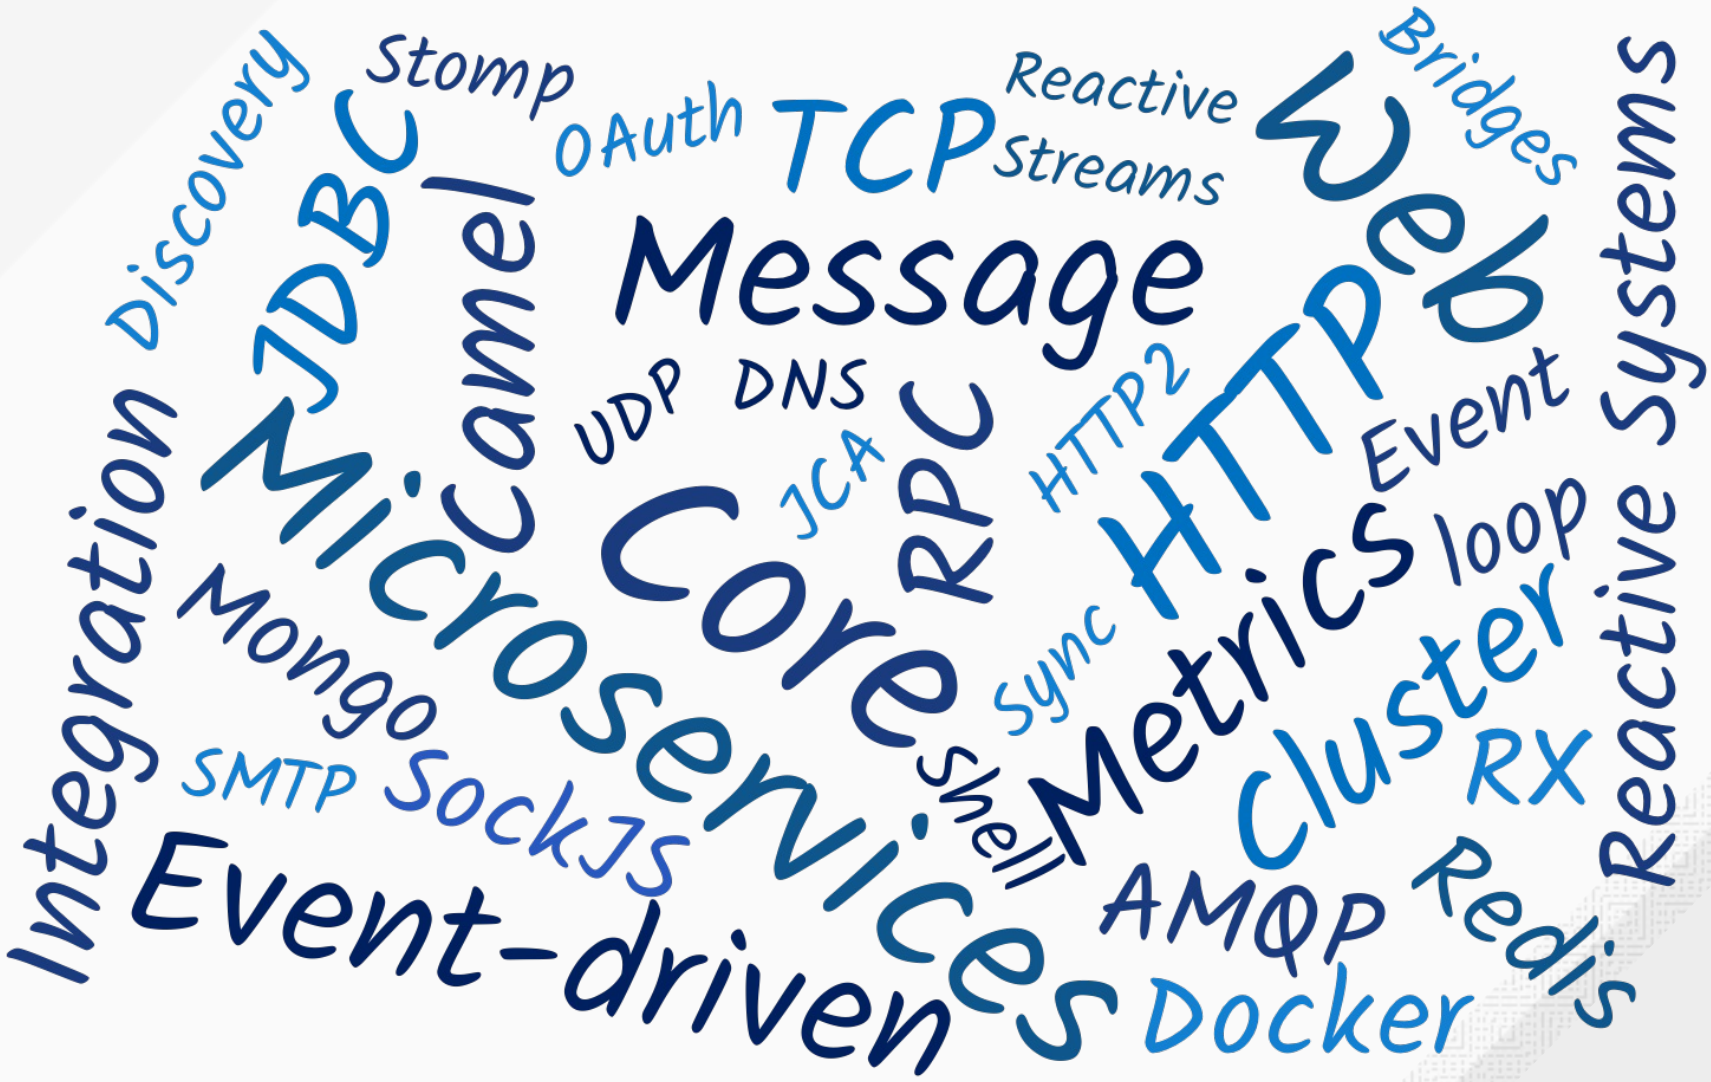
TECHEMPOWER - FORTUNE

Request -> JDBC (query) -> Template engine -> Response



THIS IS NOT THE END();

But the first step on the Vert.x path



Discovery
Stomp
OAuth
